Abstract

For effective utilization of the available spectrum and for preventing the channel interference among the users the sensing of the availability of spectrum becomes an essential task in case of Cognitive Radio Networks. Due to the effect of shadowing, fading, and uncertainty in the receiver, the overall performance of the spectrum sensing technique was compromised. Utilizing the spatial diversity of the nodes the above mentioned issues can be overcome by following a cooperative spectrum sensing approach. This approach slightly increases the overhead and the time consumed for sensing the spectrum. This work introduces a technique to check the availability of spectrum based on cooperative approach wherein the problem of sensing the spectrum is formulated as a classification task. The secondary units transfer the modulated signal present in the channel to the primary unit which estimates the spectrogram of the same and sends it to a trained convolution neural network model to detect whether it is a signal or noise. The efficiency of the cooperative sensing approach is analysed based on the accuracy in detection and the probability of detection under multiple levels of Signal to Noise Ratio levels.

Spectrum sensing allows cognitive radio systems to detect relevant signals in despite the presence of severe interference. Most of the existing spectrum sensing techniques use a particular signal-noise model with certain assumptions and derive certain detection performance. To deal with this uncertainty, learnin...

The majority of recently developed approaches require a significant number of labelled samples. The proposed system are dedicated to using less marked samples for automatic modulation detection in the cognitive radio domain. The proposed signal classifier generative adversarial nets (GANs) methodology...
